

CS41 Homework 1

This homework is due at 11:59PM on Sunday, September 13. Write your solution using L^AT_EX. Submit this homework using **github**. This is an individual homework. It's ok to discuss approaches at a high level. In fact, we encourage you to discuss general strategies. However, you should not reveal specific details of a solution, nor should you show your written solution to anyone else. The only exception to this rule is work you've done with a lab partner *while in lab*. In this case, note (in your **README file**) who you've worked with and what parts were solved during lab.

The main **learning goals** of this lab are to (i) familiarize you with the tools we'll use for remote instruction, especially L^AT_EX, (ii) review git and make sure you know how to grab/handin homeworks using git, and (iii) begin to formalize and analyze algorithms.

1. Slack and Piazza.

- (a) Log onto slack, go to the #movies channel, and say what your favorite movie is.
- (b) Log onto Piazza and either ask a question, or respond to an existing post. Don't feel like your question/post has to be about computer science! The goal is just to make sure you're comfortable using Piazza.

2. Algorithm Analysis. Consider the following algorithm for the Hiking Problem.

```
HIKING()
1  k = 1.
2  while you haven't arrived at your friend:
3      hike k miles north
4      return to start
5      hike k miles south
6      return to start
7      k = 7k.
```

Describe the distance traveled in HIKING as a function of the initial distance from your friend in the worst case. Express your answer in big-Oh notation. How does this algorithm compare to the algorithms we saw in class and lab?

3. Algorithm Design. Choose a problem you encounter in everyday life (e.g. how to get from your dorm room to Sharples by 8:30AM, or how to get into college) and describe an algorithm for solving that problem.

Be as specific and descriptive as you can.

4. (extra challenge problem) We discussed in lab a reason why m is a lower bound for the Hiking Problem. Show that $3m$ is a lower bound for the Hiking Problem.

5. (extra challenge problem) In lab we argued that updating $k \leftarrow 2k$ is more efficient than $k \leftarrow k + 1$. However, why stop there? Would it be more efficient to increase k even more rapidly? Consider the following algorithm for the Hiking Problem.

EXTREMEHIKING()

```
1   $k = 1$ .
2  while you haven't arrived at your friend:
3      hike  $k$  miles north
4      return to start
5      hike  $k$  miles south
6      return to start
7       $k = k^2$ .
```

Again, describe the distance traveled in HIKING as a function of the initial distance from your friend in the worst case. Express your answer in big-Oh notation. How does this algorithm compare to the algorithms we saw in class?
