CS 31: Intro to Systems C Programming
L13-14: Arrays, Structs, Strings, and Pointers

Vasanta Chaganti & Kevin Webb
Swarthmore College
Oct 26 – 31, 2023
Announcements

• HW 3 is due today before class
Today

• Accessing *things* via an offset
  • Arrays, Structs, Unions
  • Connect accessing them in C with what we know about assembly

• How complex structures are stored in memory
  • Multi-dimensional arrays & Structs
Reading Quiz
So far: Primitive Data Types

- We’ve been using ints, floats, chars, pointers

- Simple to place these in memory:
  - They have an unambiguous size
  - They fit inside a register*
  - The hardware can operate on them directly

(*There are special registers for floats and doubles that use the IEEE floating point format.)
Composite Data Types

• Combination of one or more existing types into a new type. (e.g., an array of multiple ints, or a struct)
Composite Data Types

• Combination of one or more existing types into a new type. (e.g., an array of multiple ints, or a struct)

• Example: a queue
  – Might need a value (int) plus a link to the next item (pointer)

```c
struct queue_node{
  int value;
  struct queue_node *next;
}
```
Recall: Arrays in Memory

```c
int *iptr = NULL;
iptr = malloc(4 * sizeof(int));
```
• We know that arrays act as a pointer to the first element. For bucket [N], we just skip forward N.
We know that arrays act as a pointer to the first element. For bucket [N], we just skip forward N.

```
int val[5];
```

```
0th bucket | 1st bucket | 2nd bucket | 3rd bucket | 4th bucket
```

This is why we start counting from zero! Skipping forward with an offset of zero ([0]) gives us the first bucket...
Which expression would compute the address of iptr[3]?

A. 0x0824 + 3 * 4
B. 0x0824 + 4 * 4
C. 0x0824 + 0xC
D. More than one (which?)
E. None of these
Which expression would compute the address of `iptr[3]`?

A. $0x0824 + 3 \times 4$
B. $0x0824 + 4 \times 4$
C. $0x0824 + 0xC$
D. More than one (which?)
E. None of these

What if this isn’t known at compile time?
Recall Addressing Mode: Memory

• Accessing memory requires you to specify which address you want.
  – Put the address in a register.
  – Access the register with () around the register’s name.

\[
\text{mov (rcx), rax}
\]
  – Use the address in register rcx to access memory, store result in register rax
Recall Addressing Mode: Displacement

• Like memory mode, but with a constant offset
  – Offset is often negative, relative to %rbp

\texttt{mov -24(\%rbp), \%rax}

  – Take the address in %rbp, subtract 24 from it, index into memory and store the result in %rax.
Addressing Mode: Indexed

• Instead of only using one register to store the base address of a memory address, we can use a base address register and an offset register value.

\[
mov (\%rax, \%rcx), \%rdx
\]

– Take the base address in \%rax, add the value in \%rcx to produce a final address, index into memory and store the result in \%rdx.
Addressing Mode: Indexed

The offset (\%rcx) can also be scaled by a constant.

\textbf{mov (\%rax, \%rcx, 4), \%rdx}

- Take the base address: \%rax
- Multiply the offset by the scale: \%rcx \times 4
- Add the scaled offset to the base: \%rax + \%rcx \times 4
- Now, index into memory at (\%rax + \%rcx \times 4) and store the result in \%rdx.
Let’s try an example

Suppose:

```c
int iptr; is stored in register %rax.
int i=2; is stored at %rbp-8
iptr[i] = 9; //iptr[2] = 9;
```

In assembly:

```assembly
mov -8(%rbp), %rcx
mov %rdx, (rax, rcx, 4)
```

```
<table>
<thead>
<tr>
<th>Heap</th>
<th>0x0824: iptr[0]</th>
<th>0x0828: iptr[1]</th>
<th>0x082C: iptr[2]</th>
<th>0x0830: iptr[3]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Registers</td>
<td>rax 0x0824</td>
<td>rcx</td>
<td>rdx 9</td>
<td></td>
</tr>
</tbody>
</table>
```

rax: Array base address

Let's try an example
Let’s try an example

Suppose:

```c
int iptr; is stored in register %rax.
int i=2; is stored at %rbp-8
iptr[i] = 9; //iptr[2] = 9;
```

In assembly:

```assembly
mov -8(%rbp), %rcx
mov %rdx, (rax, rcx, 4)
```

```
<table>
<thead>
<tr>
<th>Heap</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0824:</td>
<td>iptr[0]</td>
</tr>
<tr>
<td>0x0828:</td>
<td>iptr[1]</td>
</tr>
<tr>
<td>0x082C:</td>
<td>iptr[2]</td>
</tr>
<tr>
<td>0x0830:</td>
<td>iptr[3]</td>
</tr>
</tbody>
</table>
```

**Registers:**

- `rax`: Array base address
- `rcx`: Index
- `rdx`: 9

Calculations:

- `rax` = `add (rcx * 4)`
- `rax` = `add (2 * 4)`
- `rax` = `add 8`
What happens when we increment i?
What changes do we make in assembly?

Suppose:

```c
int iptr; is stored in register %rax.
int i=3; is stored at %rbp-8
iptr[i] = 10; //iptr[3] = 10;
```

In assembly:

```assembly
mov -8(%rbp), %rcx
mov %rdx, (rax, rcx, 4) = add (rcx * 4) = add (2*4) = add 8
```

```
<table>
<thead>
<tr>
<th>Address</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0824:</td>
<td>iptr[0]</td>
</tr>
<tr>
<td>0x0828:</td>
<td>iptr[1]</td>
</tr>
<tr>
<td>0x082C:</td>
<td>iptr[2]</td>
</tr>
<tr>
<td>0x0830:</td>
<td>iptr[3]</td>
</tr>
</tbody>
</table>
```

Registers:

-rax: Array base address

-rcx: Index

-rdx: Offset (4 bytes)
Suppose:

```c
int iptr;
int i = 3;
```

```c
iptr[i] = 10; // iptr[3] = 10;
```

In assembly:

```assembly
mov -8(%rbp), %rcx
mov %rdx, (rax, rcx, 4)
```

What happens when we increment `i`?

What changes do we make in assembly?

**Compiler can simply increment register `rcx` and access the next element of the array with the same assembly commands!**

### Registers:

<table>
<thead>
<tr>
<th></th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>rax</code></td>
<td>0x0824</td>
</tr>
<tr>
<td><code>rcx</code></td>

</table>
Two-dimensional Arrays

• Why stop at an array of ints? How about an array of arrays of ints?

\texttt{int\ twodims[3][4];}

• “Give me three sets of four integers.”

• How should these be organized in memory?
# Two-dimensional Arrays

```c
int twodims[3][4];
for(i=0; i<3; i++) {
    for(j=0; j<4; j++) {
        twodims[i][j] = i+j;
    }
}
```

<table>
<thead>
<tr>
<th>twodims[0]</th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>

twodim[1][3]:

```
base addr + row offset (# rows * rows * sizeof(int)) + col offset
```

twodim + 1*ROWSIZE*4 + 3*4

0xf260 + 16 + 12

= 0xf27c

You do not need to convert mem index into an address for the lab!
If we declared int matrix[5][3];, and the base of matrix is 0x3420, what is the address of matrix[3][2]?

A. 0x3438  
B. 0x3440  
C. 0x3444  
D. 0x344C  
E. None of these

base addr + row offset (# rows * row_size * sizeof(data_type)) + col offset
If we declared `int matrix[5][3];`, and the base of matrix is 0x3420, what is the address of `matrix[3][2]`?

A. 0x3438
B. 0x3440
C. 0x3444
D. 0x344C
E. None of these

Mem_index = 3*3+2 = 11 (you need this for the lab)
Mem. address = 0x3420 + 11*4 (2c) = 0x344c
Dynamic Two-dimensional Array

• Given the *row-major order* layout, a "two-dimensional array" is still just a contiguous block of memory:

  • The *malloc* function returns... a pointer to a contiguous block of memory!
Dynamic Two-dimensional Array

• For this example, with three rows and four columns:

```
int *matrix = malloc(3 * 4 * sizeof(int));
```

Caveat: the C compiler doesn't know that you're planning to use this block of memory with more than one index (i.e., row and column).

Can't access: matrix[i][j]
Dynamic Two-dimensional Array

• For this example, with three rows and four columns:

```c
int *matrix = malloc(3 * 4 * sizeof(int));

// Compute the offset manually
index = i * ROWSIZE + j;
matrix[index] = ...;
```
Two-dimensional array alternative

• (Dynamically) Allocate an array of pointers. For each pointer, (dynamically) allocate an array.

• How do we get an array of pointers?
Two-dimensional array alternative

• If we want a dynamic array of ints:
  – declare int *array = malloc(N * sizeof(int))

• So... if we want an array of int pointers:
  – declare int **array = malloc(...)
Two-dimensional array alternative

• If we want a dynamic array of ints:
  – declare int *array = malloc(N * sizeof(int))

• So… if we want an array of int pointers:
  – declare int **array = malloc(N * sizeof(int *))
  – The type of array[0], array[1], etc. is: int *
  – For each one of those, we can malloc an array of ints:
    • array[0] = malloc(M * sizeof(int))
Two-dimensional array alternative

```c
int **two_d_array;

two_d_array = malloc(sizeof(int *) * N);
for (i=0; i < N; i++) {
    two_d_array[i] = malloc(sizeof(int) * M);
}
```
Two-dimensional arrays

- We'll use BOTH methods in future labs.
Structs

• Multiple values (fields) stored together
  – Defines a new type in C's type system

• Laid out contiguously by field (with a caveat we'll see later)
  – In order of field declaration.
**Structs**

Laid out contiguously by field (with a caveat we'll see later)
– In order of field declaration.

```c
struct student{
    int age;
    float gpa;
    int id;
};

struct student s;
```
Structs

Struct fields accessible as a base + displacement
– Compiler knows (constant) displacement of each field

```c
struct student{
    int  age;
    float gpa;
    int   id;
};

struct student s;
```
Structs

Struct fields accessible as a base + displacement
– Compiler knows (constant) displacement of each field

```c
struct student{
    int age;
    float gpa;
    int id;
};

struct student s;
```

Given the starting address of a struct...

The id field is always at an offset of 8 forward from the start.
Structs

Struct fields accessible as a base + displacement
In assembly: mov reg_value, 16(reg_base)

Where:
• reg_value is a register holding the value to store (say, 12)
• reg_base is a register holding the base address of the struct

```
struct student{
    int age;
    float gpa;
    int id;
};

struct student s;
s.id = 12;
```

Memory

<table>
<thead>
<tr>
<th>0x1234</th>
<th>s.age</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x1238</td>
<td>s.gpa</td>
</tr>
<tr>
<td>0x123c</td>
<td>s.id</td>
</tr>
</tbody>
</table>

Given the starting address of a struct...
The id field is always at an offset of 8 forward from the start.
Structs

• Laid out contiguously by field
  – In order of field declaration.
  – May require some padding, for data alignment.

Memory:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x1234</td>
<td>s.age</td>
</tr>
<tr>
<td>0x1238</td>
<td>s.gpa</td>
</tr>
<tr>
<td>0x123c</td>
<td>s.id</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>
Data Alignment:

• Where (which address) can a field be located?

• **char (1 byte):** can be allocated at any address:
  - 0x1230, 0x1231, 0x1232, 0x1233, 0x1234, ...

• **short (2 bytes):**
  - must be aligned on 2-byte addresses:
  - 0x1230, 0x1232, 0x1234, 0x1236, 0x1238, ...

• **int (4 bytes):**
  - must be aligned on 4-byte addresses:
  - 0x1230, 0x1234, 0x1238, 0x123C, 0x1240, ...
Why do we want to align data on multiples of the data size?

A. It makes the hardware faster.

B. It makes the hardware simpler.

C. It makes more efficient use of memory space.

D. It makes implementing the OS easier.

E. Some other reason.
Why do we want to align data on multiples of the data size?

A. It makes the hardware faster.

B. It makes the hardware simpler.

C. It makes more efficient use of memory space.

D. It makes implementing the OS easier.

E. Some other reason.
Data Alignment: Why?

- Simplify hardware
  - e.g., only read ints from multiples of 4
  - Don’t need to build wiring to access 4-byte chunks at any arbitrary location in hardware

- Inefficient to load/store single value across alignment boundary (1 vs. 2 loads)

- Simplify OS:
  - Prevents data from spanning virtual pages
  - Atomicity issues with load/store across boundary
Structs

- Laid out contiguously by field
  - In order of field declaration.
  - May require some padding, for alignment.

```c
struct student{
    int age;
    float gpa;
    int id;
};

struct student s;
```
struct student{
    char name[11];
    short age;
    int id;
};
How much space do we need to store one of these structures? Why?

```
struct student{
    char name[11];
    short age;
    int id;
};
```

A. 17 bytes
B. 18 bytes
C. 20 bytes
D. 22 bytes
E. 24 bytes
struct student{
    char name[11];
    short age;
    int id;
};

size of data: 17 bytes
size of struct: 20 bytes!

Use sizeof() when allocating structs with malloc()!
(struct student{
    char name[11];
    short age;
    int id;
};)
Alternative Layout

```c
struct student{
    char name[11];
    short age;
    int id;
};
```

size of data: 17 bytes

size of struct: 17 bytes

In general, this isn’t a big deal on a day-to-day basis. Don’t go out and rearrange all your struct declarations.
Aside: Network Headers

• In networks, we attach metadata to packets
  – Things like destination address, port #, etc.

• Common for these to be a specific size/format
  – e.g., the first 20 bytes must be laid out like ...

• Naïvely declaring a struct might introduce padding, violate format.
Cool, so we can get rid of this struct padding by being smart about declarations?

A. Yes (why?)

B. No (why not?)
Cool, so we can get rid of this padding by being smart about declarations?

- Answer: Maybe.

- Rearranging helps, but often padding after the struct can’t be eliminated.

```
struct T1 {
    char c1;
    char c2;
    int x;
};
```

```
struct T2 {
    int x;
    char c1;
    char c2;
};
```
“External” Padding

Array of Structs: Field values in each bucket must be properly aligned:

```
struct T2 arr[3];
```

Buckets must be on a 8-byte aligned address
struct student {
    int id;
    short age;
    char name[11];
};
struct student s;

s.id = 406432;
s.age = 20;
strcpy(s.name, "Alice");
struct student {
    int id;
    short age;
    char name[11];
};

struct student *s = malloc(sizeof(struct student));

What about this?

How do we get to the id and age?
struct student {
    int id;
    short age;
    char name[11];
};

struct student *s = malloc(sizeof(struct student));

What about this?

How do we get to the id and age?

Option 1: Works but ugly

(*s).id = 406432;
(*s).age = 20;
strcpy((*s).name, "Alice");

Option 2: Use struct pointer dereference!

s->id = 406432;
s->age = 20;
strcpy(s->name, "Alice");
Memory alignment applies elsewhere too!

```c
int x; vs. double y;
char ch[5]; int x;
short s; short s;
double y; char ch[5];
```

In nearly all cases, *you shouldn't stress about this*. The compiler will figure out where to put things.

Exceptions: networking, OS
Unions

- Declared like a struct, but only contains one field, rather than all of them.

- Struct: field 1 and field 2 and field 3 ...
- Union: field 1 or field 2 or field 3 ...

Intuition: you know you only need to store one of N things, don’t waste space.
Unions

struct my_struct {
    char ch[2];
    int i;
    short s;
}

union my_union {
    char ch[2];
    int i;
    short s;
}

Same memory used for all fields!
Unions

```c
my_union u;

u.i = 7;

union my_union {
    char ch[2];
    int i;
    short s;
}
```

Same memory used for all fields!
Unions

```c
my_union u;

u.i = 7;
u.s = 2;
```

```c
union my_union {
  char ch[2];
  int i;
  short s;
}
```

Same memory used for all fields!

my_union in memory
Unions

```c
my_union u;

u.i = 7;
u.s = 2;
u.ch[0] = 'a';

u.i = 5;
```

Reading `i` or `s` here would be bad!

Same memory used for all fields!
Unions

my_union u;

u.i = 7;

u.s = 2;

u.ch[0] = 'a';

u.i = 5;

union my_union {
    char ch[2];
    int i;
    short s;
}

Reading i or s here would be bad!
Unions

• You probably won’t use these often.

• Use when you need mutually exclusive types.

• Can save memory.

```c
union my_union {
  char ch[2];
  int i;
  short s;
}
```

Same memory used for all fields!
Strings

• Strings are *character arrays*

• Layout is the same as:
  – char name[10];

• Often accessed as (char *)
String Functions

- C library has many built-in functions that operate on char *’s:
  - strcpy, strdup, strlen, strcat, strcmp, strstr

```c
char name[10];
strcpy(name, "CS 31");
```
String Functions

• C library has many built-in functions that operate on char *’s:
  – strcpy, strdup, strlen, strcat, strcmp, strstr

```c
char name[10];
strcpy(name, “CS 31”);
```

• Null terminator (\0) ends string.
  – We don’t know/care what comes after
String Functions

• C library has many built-in functions that operate on char *’s:
  – strcpy, strdup, strlen, strcat, strcmp, strstr

• Seems simple on the surface.
  – That null terminator is tricky, strings error-prone.
  – Strings used everywhere!

• You will implement use these functions in a future lab.
Up next…

• New topic: Storage and the Memory Hierarchy
