Lab 3: Algorithm Analysis

Due: Sunday, September 29th at noon; NO LATE DAYS

Overview

In this lab, you will answer several math and algorithm questions and complete the mystery function exercise. You will submit a <u>hard copy</u> of this lab. You may type your solution, if you wish. **This is an individual** lab. You can retrieve requisite code from update35 for the mystery function portion of the lab.

Deliverables

Your submission should be **concise and easy to read**. You should answer all 5 short answer questions, the run times of all 6 functions, written support of the mapping to mystery functions, and at-least two print out of graphs to support that argument.

Submission

You will submit this lab in <u>hard copy</u> to my mail slot outside my office, Science 253. Sorry, no late labs will be accepted for this lab since the quiz study session Sunday night will go over answers.

Short Answer Questions

1. Justify the following Big-O for the given functions:

```
(a) 3n^4 - 2n^3 + 10 is O(n^4)
(b) \frac{1}{2}n - lg(n) is O(n)
```

2. Prove the following claims by induction:

```
(a) \forall n > 1, \quad n^3 > n^2

(b) \forall n > 1, \quad \sum_{i=1}^{n} i^2 = \frac{n(n+1)(2n+1)}{6}
```

3. Using loop-invariants/induction, prove that the isSorted function from class correctly verifies that an array A is sorted in ascending order. HINT: Formally, you are trying to prove S: A is sorted in ascending order.

```
function IsSORTED(A, size)
for i \leftarrow 0 \dots size - 2 do
if A[i] > A[i+1] then
return False
end if
end for
return True
end function
```

- 4. (C-4.23 from Goodrich et. al) An evil king has n bottles of wine, and a spy has just poisoned one of them. Unfortunately, the king doesn't know which bottle it is. The poison is very deadly; just one drop diluted even a billion to one will still kill. Even so, it takes a full month for the poison to take effect. Design a scheme for determining exactly which one of the wine bottles was poisoned in just one month's time while utilizing $O(\log n)$ taste testers. Make a short argument for what you think the run time of your technique is, even if you cannot come up with an optimal solution. Please, keep solution to a paragraph or less.
- 5. Describe an algorithm for finding both the minimum and maximum (simultaneously) of n numbers using fewer than 3n/2 comparisons of elements in A. The following pseudocode finds the max using n-1 comparisons.

```
def findMax(Array A, size n>0):
   max=A[0]
   for i in 1 to n (inclusive)
     if(A[i] > max)
        max=A[i]
   return max
```

Mystery Functions

In this part of the lab, you will first analyze six simple loop structures and determine their run time performance in terms of Big-O. Then, using the provided program function_timer, you will graph the empirical run times of these functions.

Functions

To begin, identify the Big-O run time for each of the following 6 functions. You do not need to provide a justification, simply write the function name followed by the Big-O on your solution. Use the strictest Big-O (i.e., the closest upper bound) and ignore all but the most significant term (e.g. **Ex 7:** $O(\log n)$).

```
Ex1(n)
  for (i=0; i<n; i++) {</pre>
    a=i;
Ex2(n)
 for(i=0; i<n; i+=2){</pre>
    a=i;
Ex3(n)
  for(i=0; i<n*n; i++) {</pre>
    a=i;
Ex4(n)
  for(i=0; i<n; i++) {</pre>
    for(j=0; j<=i; j++){
         a=i;
  }
Ex5(n)
  for (i=0; i<n*n; i++) {</pre>
    for(j=0; j<=i; j++) {</pre>
      a=i;
Ex6(n)
  for(i=0; i<n; i++) {</pre>
    for(j=0; j<=k; j++){
       a=j;
    k=k*2;
```

Decoding functions using function_timer

Each of the above functions has implemented and packaged in the executable function_timer, which has placed in your lab directory for this week. This program will provide an empirical run-time for each method and plots them automatically using the unix tool gnuplot.

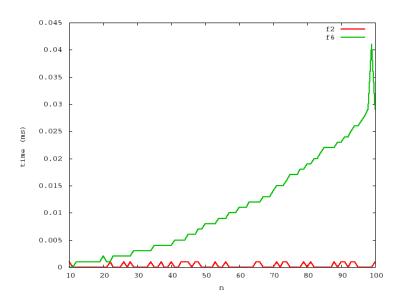

To begin, here is the usage (this is an abbreviated version; obtain more details on the command line):

The key choices you have to make are:

- Which function(s) to plot. To plot func1, add -1 as a command line argument. To plot func2 vs func3, add -2 -3, etc.
- The minimum and maximum values for n. You should recall from lecture that n may have to be very large for fast algorithms and small for slow ones. One size definitely does not fit all.
- Whether to save to file or immediately load plot. You'll want to save once you get a result you like using the -s option.

For example, you can compare functions 2 and 6 from $n=10\dots 100$ and output the result:

```
$ ./function_timer -2 -6 -s out.png -n 10 -m 100 | gnuplot
```

Note that you must 'pipe' the output of the program to the plotting program, gnuplot. This is done using the vertical bar |, which simply sends the output from function_timer straight to gnuplot.

Now here is the twist: I've jumbled up the ordering of functions in function_timer. Your job is to figure out the mapping from the functions in function_timer (e.g., -1, -2, ...) to their corresponding number above (e.g., Ex1, Ex2, ...). In addition to **determining the mapping between mystery functions and the functions above, you must support your argument in writing for each and provide a graph to support two of your mappings in your hard-copy submission.**
